(a) Frame camera → vision encoder

RGB frames every 33 ms (30 fps)

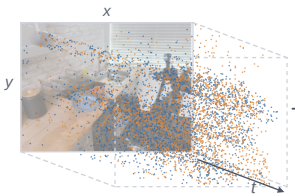

all H×W pixels, every frame

vision encoder

33 ms resolution, motion blur
dense compute on every frame

(b) DVS → accumulate events into a frame → fuse with RGB → vision encoder

event stream (x, y, t, p)

sum ΔT

event frame (ΔT = 6 ms)

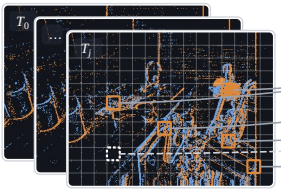

RGB frame

concat

vision encoder

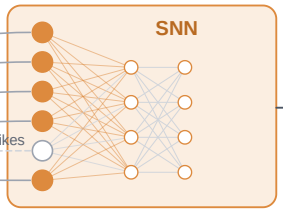

events re-binned into frames
sparsity and µs timing lost

(c) DVS → spiking neural network: purely event-driven

event stream on the pixel grid

one spike train per pixel

compute only on spikes
static pixels: no spikes, no compute
